# Solana Blockchain Developer Bootcamp Outline

## Day 1: Introduction

Learn about Solana, its architecture and programming model. Build some example smart contracts such as a simple GM, and a token contract.

## Day 2: Anchor and Chainlink

Learn how to use the Anchor framework, as well as how to use Chainlink Price Feeds to get pricing data in your Solana smart contracts

# Housekeeping Rules

- 3 hour session, broken up into sections, with breaks
- Presentation, followed by questions, demo and exercises
- Questions can be asked at the end of each section
- Zoom: If you need help during a practical exercise, raise your hand and an instructor will eventually get to you and send you an invite to a private breakout session 
- Technical questions can be asked in the chat or in the #developer-bootcamp channel in the Chainlink Discord

# Day 2 Exercises

- Exercise requirements:
  - [NodeJS](#)
  - [Rust](#)
  - [Solana Tool Suite](#)
  - [Visual Studio Code](#)
  - [Anchor](#)

# Agenda: Day 2

- 1. **Introduction to Anchor**
- 2. Exercise: GM Anchor Program
- 3. Exercise: Solana Social
- 4. The Oracle Problem and Chainlink
- 5. Exercise: Price Feeds Consumer Program
- 6. Where You Can Learn More
- 7. Summary

# Introduction to Anchor

# Anchor

- A framework for quickly building secure Solana programs
- Reduces coding efforts by generating various boilerplate code
- Handles security checks

# Anchor Projects

- Serum
- Synthetify
- Mango IDO
- Metaplex Candy Machine
- SolFarm
- Saber
- Solend
- Jet Protocol
- Quarry
- PsyOptions
- Arrow Protocol
- Hubble Protocol
- + many more

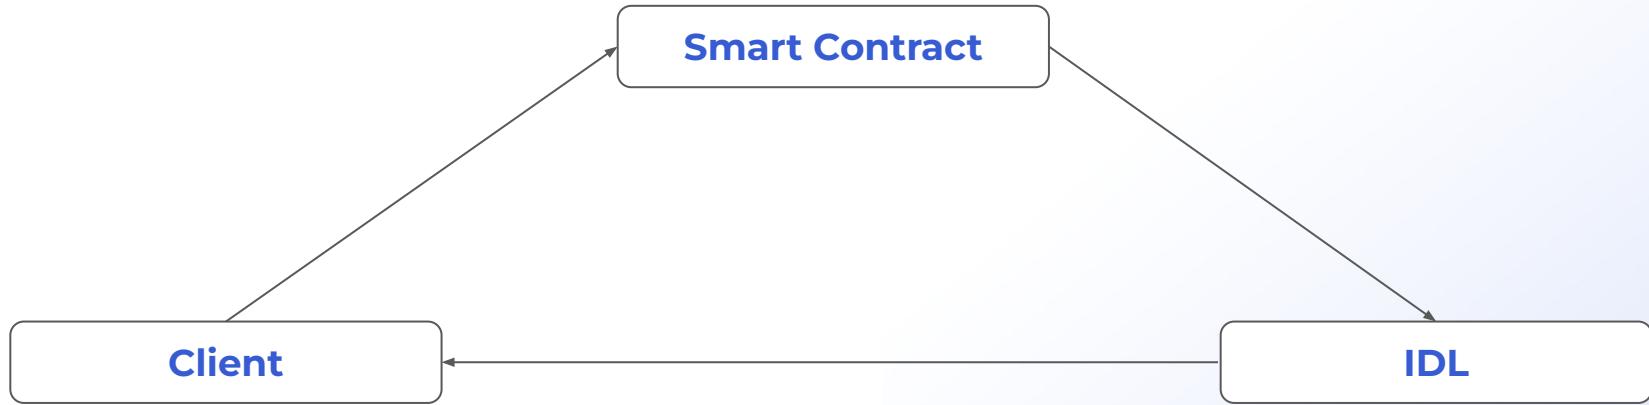

# Anchor Tools

- Rust smart contracts
- Interface Description Language
- Client Generators
- CLI

# Anchor Workflow

# Anchor High Level Overview

- Anchor program consists of three parts:
  - Program module
    - Where the program logic is written
  - Accounts structs
    - Where accounts are validated
  - Declare ID macro
    - Stores the address of the program

# Anchor High Level Overview

```
use anchor_lang::prelude::*;

// declare an id for your program
declare_id!("Fg6PaFpoGXkYsidMpWTK6W2BeZ7FEfcYkg476zPFsLnS");

// write your business logic here
#[program]
mod hello_anchor {
    use super::*;

    pub fn initialize(_ctx: Context<Initialize>) -> ProgramResult {
        Ok(())
    }
}

// validate incoming accounts here
#[derive(Accounts)]
pub struct Initialize {}
```

# Anchor: Accounts

- Where you define which accounts your instruction expects, and which constraints these accounts should follow
  - Types
    - [Various account types](#)
  - Constraints
    - Handles security and access control for accounts

# Anchor: Account Type

- Used when an instruction is interested in the deserialized data of an account.

# Anchor: Accounts

```
use anchor_lang::prelude::*;

declare_id!("Fg6PaFpoGXkYsidMpWTK6W2BeZ7FEfcYkg476zPFsLnS");

#[program]
mod hello_anchor {
    use super::*;

    pub fn set_data(ctx: Context<SetData>, data: u64) -> ProgramResult {
        ctx.accounts.my_account.data = data;
        Ok(())
    }
}

#[account]
#[derive(Default)]
pub struct MyAccount {
    data: u64
}

#[derive(Accounts)]
pub struct SetData<'info> {
    #[account(mut)]
    pub my_account: Account<'info, MyAccount>
}
```

# Anchor: Constraints

- Accounts aren't dynamic enough to handle all the security checks required
- Constraints can be added to dynamically perform checks and validation

```
# [account (<constraints>) ]  
pub account: AccountType
```

```
# [derive(Accounts) ]  
pub struct SetData<'info> {  
    #[account(mut)]  
    pub my_account: Account<'info, MyAccount>,  
    #[account(  
        constraint = my_account.mint == token_account.mint,  
        has_one = owner  
    )]  
    pub token_account: Account<'info, TokenAccount>,  
    pub owner: Signer<'info>  
}
```

# Anchor: Program Module

- Where business logic is defined
- Write functions which can then be called by clients or other programs
- Each defined endpoint takes a **Context** type as an argument
  - Provides access to the accounts of the executing program and the Program ID

```
# [program]
mod hello_anchor {
    use super::::*;
    pub fn set_data(ctx: Context<SetData>, data: u64) ->
ProgramResult {
        if ctx.accounts.token_account.amount > 0 {
            ctx.accounts.my_account.data = data;
        }
        Ok(())
    }
}
```

# Anchor: Instruction Data

- Can be added by adding arguments to the function after the context argument
- Anchor will automatically deserialize the instruction data into the arguments

# Anchor: Instruction Data

```
# [program]
mod hello_anchor {
    use super::.*;
    pub fn set_data(ctx: Context<SetData>, val: u64) ->
ProgramResult {
    ctx.accounts.data.val = val;
    Ok(())
}
}

#[account]
#[derive(Default)]
pub struct Data {
    pub val: u64
}
```

# Anchor: IDL

- Generates an [IDL](#) specification for programs
  - Similar to an EVM-based ABI
- Used by clients to be able to interact with deployed Anchor-based programs
- Greatly simplifies calling functions, sending and receiving data
- Acts as the connecting glue between the on-chain program, and off chain clients

# Anchor: IDL

```

use anchor_lang::prelude::*;

declare_id!("Fg6PaFpoGXkYsidMpWTK6W2BeZ7FEfcYkg476zPFsLnS");

#[program]
mod basic_1 {
    use super::*;

    pub fn initialize(ctx: Context<Initialize>, data: u64) -> ProgramResult {
        let my_account = &mut ctx.accounts.my_account;
        my_account.data = data;
        Ok(())
    }
}

#[derive(Accounts)]
pub struct Initialize<'info> {
    #[account(init, payer = user, space = 8 + 8)]
    pub my_account: Account<'info, MyAccount>,
    #[account(mut)]
    pub user: Signer<'info>,
    pub system_program: Program<'info, System>,
}

#[account]
pub struct MyAccount {
    pub data: u64,
}

```

# Anchor: IDL

```
{  
  "version": "0.1.0",  
  "name": "basic_1",  
  "instructions": [  
    {  
      "name": "initialize",  
      "accounts": [  
        {"name": "myAccount", "isMut": true, "isSigner": true},  
        {"name": "user", "isMut": true, "isSigner": true}  
        {"name": "systemProgram", "isMut": true, "isSigner": true}],  
      "args": [  
        {  
          "name": "data",  
          "type": "u64"  
        }  
      ]}],  
  "accounts": [  
    {  
      "name": "MyAccount",  
      "type": {  
        "kind": "struct",  
        "fields": [  
          {"name": "data", "type": "u64"}  
        ]  
      }  
    }  
  ]  
}
```

# Anchor: Generating a Client using IDL

```
// Read the generated IDL.  
const idl = JSON.parse(  
  require("fs").readFileSync("./target/idl/basic_1.json", "utf8")  
)  
  
// Address of the deployed program.  
const programId = new anchor.web3.PublicKey("<YOUR-PROGRAM-ID>");  
  
// Generate the program client from IDL.  
const program = new anchor.Program(idl, programId);  
  
// The Account to create.  
const myAccount = anchor.web3.Keypair.generate();  
  
// Create the new account and initialize it with the program.  
await program.rpc.initialize(new anchor.BN(1234), {  
  accounts: {  
    myAccount: myAccount.publicKey,  
    user: provider.wallet.publicKey,  
    systemProgram: SystemProgram.programId,  
  },  
  signers: [myAccount],  
});
```

# Anchor: Building and Deploying Programs

```
anchor build
```

- Builds programs in the workspace targeting Solana's BPF runtime and emitting IDLs in the target/idl directory

# Anchor: Building and Deploying Programs

```
anchor deploy [cluster]
```

- Deploys all programs in the workspace to the configured cluster.
- Optional cluster parameter ‘provider.cluster’
  - devnet, testnet, mainnet-beta, localnet

# Anchor: Building and Deploying Programs

```
anchor new [program-name]
```

- Initializes a project workspace with the following structure.
  - *Anchor.toml*: Anchor configuration file.
  - *Cargo.toml*: Rust workspace configuration file.
  - *package.json*: JavaScript dependencies file.
  - *programs/*: Directory for Solana program crates.
  - *app/*: Directory for your application frontend.
  - *tests/*: Directory for JavaScript integration tests.
  - *migrations/deploy.js*: Deploy script.

# Anchor: Building and Deploying Programs

```
anchor init
```

- Creates a new program in the workspace's programs/ directory initialized with boilerplate code

# Anchor: Building and Deploying Programs

```
anchor verify [program-id]
```

- Verifies the on-chain bytecode matches the locally compiled artifact.

# Testing With Anchor

```
anchor test
```

- Run an integration test suite against the configured cluster, deploying new versions of all workspace programs before running them.
  - Looks for a [test] script definition in the Anchor.toml file
- If the configured network is a localnet, then automatically starts the local network and runs the test.

## Exercise 1: GM Anchor Program

- Program that accepts a name parameter, says GM to it and stores the name in an account
- 30 minutes

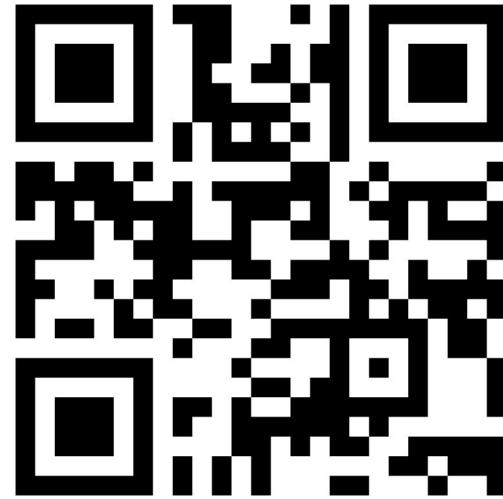

## Exercise 2: Solana Social Program

- Social Media posts on Solana
  - Create post
  - Update post
- 60 minutes

# Where Can You Learn More

## Cooking with Solana

The *Solana Cookbook* is a developer resource that provides the essential concepts and references for building applications on Solana. Each concept and reference will focus on specific aspects of Solana development while providing additional details and usage examples.

## Contributing

The Cookbook is designed in a way that makes it easy for new Solana developers to contribute. Even if you don't know how to do something, contributing to the cookbook is a great way to learn!

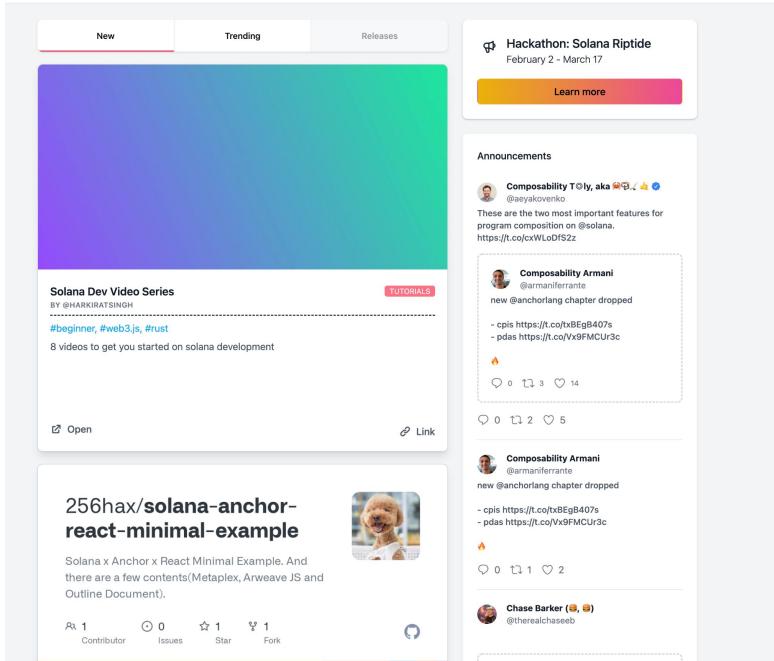

Check out all open issues [here](#). Contribution guidelines [here](#). If you find the cookbook is missing a suggestion, please add an issue.

## How to Read the Cookbook

The Solana Cookbook is split into different sections, each aimed at a different goal.

Section	Description
Core Concepts	Building blocks of Solana that are good to know for development
Guides	Snack-sized guides about different tools for development
References	References to commonly needed code snippets

# Solana Starter Kit

## Chainlink Solana Starter Kit

The Chainlink Solana Starter Kit is an [Anchor](#) based program and client that shows developers how to use and interact with [Chainlink Price Feeds on Solana](#). The demo is configured to run on the [Devnet cluster](#), and is comprised of an on-chain program written in Rust, and an off-chain client written in JavaScript. The program takes parameters and account information from the off-chain client, retrieves the latest price data from the specified Chainlink Price Feed on Devnet, then writes the data out to the specified account, which can then be read by the off-chain client.

### Running the example on Devnet

#### Requirements

- [NodeJS 12](#) or higher
- [Rust](#)
- [Solana CLI](#)
- A C compiler such as the one included in [GCC](#).

#### Building and Deploying the Consumer Program

First, ensure that you're in the `solana-starter-kit` directory in this repository

```
cd ./solana-starter-kit
```

Next step is to install all of the required dependencies:

```
npm install
```

**Note for Apple M1 chipsets:** You will need to perform an extra step to get the Anchor framework installed manually from source, as the NPM package only supports x86\_64 chipsets currently, please run the following command to install it manually:

```
cargo install --git https://github.com/project-serum/anchor --tag v0.20.1 anchor-cli --locked
```

**docs.chain.link**

LINK Token Contracts

LINK tokens are used to pay node operators for retrieving data for smart contracts and also for deposits placed by node operators as required by contract owners.

The LINK token is an ERC20 token that inherits functionality from the ERC20 token standard and allows token transfers to contain a data payload. Read more about the [ERC20 transferAndCall token standard](#).

**DATA FEEDS**  
Using Data Feeds  
Solana Data Feeds

## Using Data Feeds (Solana)

Chainlink Data Feeds are the quickest way to connect your smart contracts to the real-world market prices of assets. For example, one use for data feeds is to enable smart contracts to retrieve the latest pricing data of an asset in a single call.

This guide applies specifically to using data feeds on [Solana](#) clusters. To get the full list of Chainlink Data Feeds on Solana, see the [Solana Feeds](#) page.

View the program that owns the Chainlink Data Feeds in the [Solana Devnet Explorer](#).

Select quality data feeds

Be aware of the quality of the data that you use. [Learn more about making responsible data quality decisions.](#)

### Overview

This guide demonstrates the following tasks:

- Write and deploy programs to the [Solana Devnet](#) cluster using Anchor.
- Retrieve data using the [Solana Web3 JavaScript API](#) with Node.js.

This example shows you how to work with a program that you deploy, but you can refactor the client section to work with a program ID of your choice.

Table of contents:

- Install the required tools
- Deploy the example program
- Call the deployed program
- Clean up

### Install the required tools

Before you begin, set up your environment for development on Solana:

- Install [Git](#) if it is not already configured on your system.
- Install [Node.js 12 or higher](#). Run `node --version` to verify which version you have installed:

```
node --version
```

- Install a C compiler such as the one included in [GCC](#). Some dependencies require a C compiler.

```
sudo apt install gcc
```

- Install [Rust](#):

```
curl --proto '=https' --tlsv1.2 -sSF https://sh.rustup.rs | sh & source $HOME/.cargo/env
```

- Install the latest Mainnet version of the [Solana CLI](#) and export the path to the CLI:

- A Verifiable Random Function (VRF) to access a provably fair and secure Random Number Generator (RNG) directly on-chain.
- Modular External Adapters to connect to any off-chain resource like premium data providers, web APIs, IoT sensors, bank payments, enterprise backends, other blockchains, and more.
- Various other oracle services such as Fair Sequencing Services for fair transaction ordering, DECO for privacy-preserving attestations of TLS web session data, Arbitrum Rollups for scalable off-chain Solidity computation, and more.

Monolithic Oracle Network

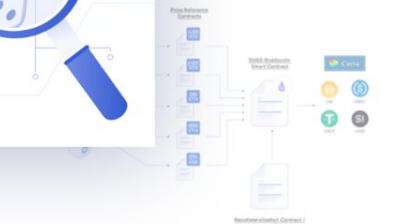

## Decentralized Finance

Money is the common medium used today to value and exchange assets. Financial products provide different vehicles in which people can maximize the value of their money via different strategies like hedging, speculating, earning interest, collateralizing loans, and more. However, traditional finance is often gated, wherein well-capitalized entities have disproportionate control over the issuance of money and products. The result is a lack of liquidity and the introduction of more influence on whether the financial agreed upon terms.

Chainlink's execution of financial products, including derivatives, and provide tamper-proof oracles play a critical role in creating financial products and monetary instruments, such as data like FX rates, interest rates, asset

Set tokens at 1:1 to fiat currency, commonly the US dollar. A non-volatile cryptocurrency, while it is off-chain bank account, decentralized stablecoin on-chain cryptocurrencies and requires a user's collateral is worth over 150%

Dai-stablecoin (a stablecoin backed by Feeds to track the price of the DAI, and USDC). In the event that one or more reserves fail, causing DUSD to also lose its peg, the four reserves in order to preserve the

Chainlink Proof of Reserve provides smart contracts proof of the Bitcoin collateral backing BitGo's Wrapped Bitcoin.

## Money Markets

Blockchain-based money markets are crucial financial infrastructure that use smart contracts to connect lenders, who wish to earn yield on their assets, with borrowers, who wish to gain access to working capital. They allow users to increase the utility of their crypto holdings and participate in both the supply and demand side. However, to ensure the solvency of the platform, price feeds are required to track the valuation of assets used on the platform as a means of ensuring loans are issued at fair market prices and liquidations automatically occur on undercollateralized loans.

Aave is an example of an on-chain money market protocol that uses Chainlink Price

Tokensets is one such example of a protocol that uses Chainlink Price feeds to generate various "Sets," tokenized positions that execute trades on the behalf of users. These Sets are based on Technical Analysis (TA) metrics such as the RSI or moving averages, designed to catch key price action trends. Additionally, users can use Set tokens as collateral within other protocols, such as the Aave money market, to unlock additional capital efficiency.

## Real-World Assets

As discussed in our recent education piece, tokenized real-world assets are among the most promising use cases for blockchain and smart contract technology. They represent real-world assets and represent them on the blockchain as a token. Compared to traditional assets, tokenized assets benefit from global accessibility, permanent liquidity, on-chain transparency, and reduced transactional friction.

## Proof of On-Chain Reserve

Wrapped cross-chain assets—cryptocurrencies/tokens native to one blockchain—are locked into a contract and then “unlocked” on another blockchain—thereby becoming increasingly popular due to their ability to increase the collateral types available within the DeFi ecosystem. However, in order to ensure the integrity of these assets, applications supporting wrapped asset deposits, Proof of Reserve reference feeds can be used to supply data regarding the true collateralization of these on-chain assets.

Two protocols using Chainlink to power Proof of Reserve reference feeds include BitGo's WBTC and Ren Protocol's renBTC, representing over 90% of the wrapped Bitcoin on Ethereum and representing millions in USD value. These Proof of Reserve reference feeds provide DeFi protocols with the data they need to autonomous collateral reserves and swiftly protect user funds during an undercollateralization event. Proof of Reserve reference feeds can also be used to track the collateralization of assets beyond cross-chain tokens includes stablecoins and real-world commodities, further increasing the collateral available within DeFi.

Chainlink Proof of Reserve provides smart contracts proof of the Bitcoin collateral backing BitGo's Wrapped Bitcoin.

## Proof of Off-Chain Reserve

Bringing real-world assets onto the blockchain provides a large potential to expand the economic activity of DeFi, as seen with the adoption of fiat-backed stablecoins. However, this requires the underlying collateral to be held by a central custodian, disconnecting the on-chain tokenized representation from the actual off-chain asset itself. Through Chainlink Proof of Reserve, smart contracts are able to automatically audit the collateralization of real-world asset backed tokens, protecting users during black swan events.

An example of this is the TUSD Proof of Reserve reference feed that provides TUSD applications with data regarding the true amount of US dollars backing the stablecoin. TUSD held by TrustToken's off-chain escrowed bank accounts as reviewed by Armanin, an independent top 25 auditing firm in the United States. This collateralization data can be checked against the total amount of circulating TUSD tokens on various blockchains, as reported by the complementary TUSD Proof of Supply feed, to determine the collateralization of TrustToken's tokenized USD.

# Solana Blockchain Developer Bootcamp Day 2 Summary

- Intro Anchor
- Writing and interacting with programs using Anchor
- The oracle problem and Chainlink
- Chainlink Data Feeds

Chainlink

SOLANA

Congratulations for completing the Solana  
Blockchain Developer Bootcamp
